

- Configured an EtherChannel (Port-Channel) connection between two Cisco Catalyst 2960 switches to combine multiple physical links into one logical connection.
- Bundled four physical Ethernet links between Switch0 and Switch1 to increase aggregate bandwidth and provide link redundancy.
- Configured the participating switch interfaces with matching EtherChannel settings to establish the port-channel connection.
- Verified the EtherChannel links and confirmed that the physical interfaces were bundled into a single logical link.
- Connected four PCs to each switch to create a small LAN environment with eight end devices.
- Observed Spanning Tree Protocol (STP) behavior to understand how redundant switch links are handled and how EtherChannel reduces the need for STP to block individual bundled links.
- Practiced Layer 2 switching concepts, link aggregation, redundancy, and switch-to-switch connectivity using Cisco Packet Tracer.
